SELFBELTING - It’s Up To You

SELFBELTING - It’s Up To You

If you use ChatGPT, or any AI copilot at work, this page is for you. Over the years since the advent of all things AI, more and more people have fallen into long rabbitholing sessions with their AI copilots, which runs the risk of cognitive decline, as researchers have discovered.

SELFBELTING is a robust paradigm made of safety-first principles and guides. Through our self-disciplinary frameworks, we treat a long AI session like a drive or a ranked game: start with a destination, keep your hands on the wheel, then stop. Company rules and “AI safety” in the model are the highway lights. SELFBELTING is the belt you buckle. It is not medical advice and not a claim that one sitting melts a brain. The left-rail button is SELFBELT; the practice on this page is SELFBELTING.

A car is not dangerous because steel is evil. It is dangerous because it covers miles in minutes. The body that evolved for walking did not get a new nervous system when the engine arrived. AI is dangerous in the same family of ways: a chatbot or image model covers hours of reading, looking, and drafting in seconds. Speed is the product. Speed is also why you need a belt.

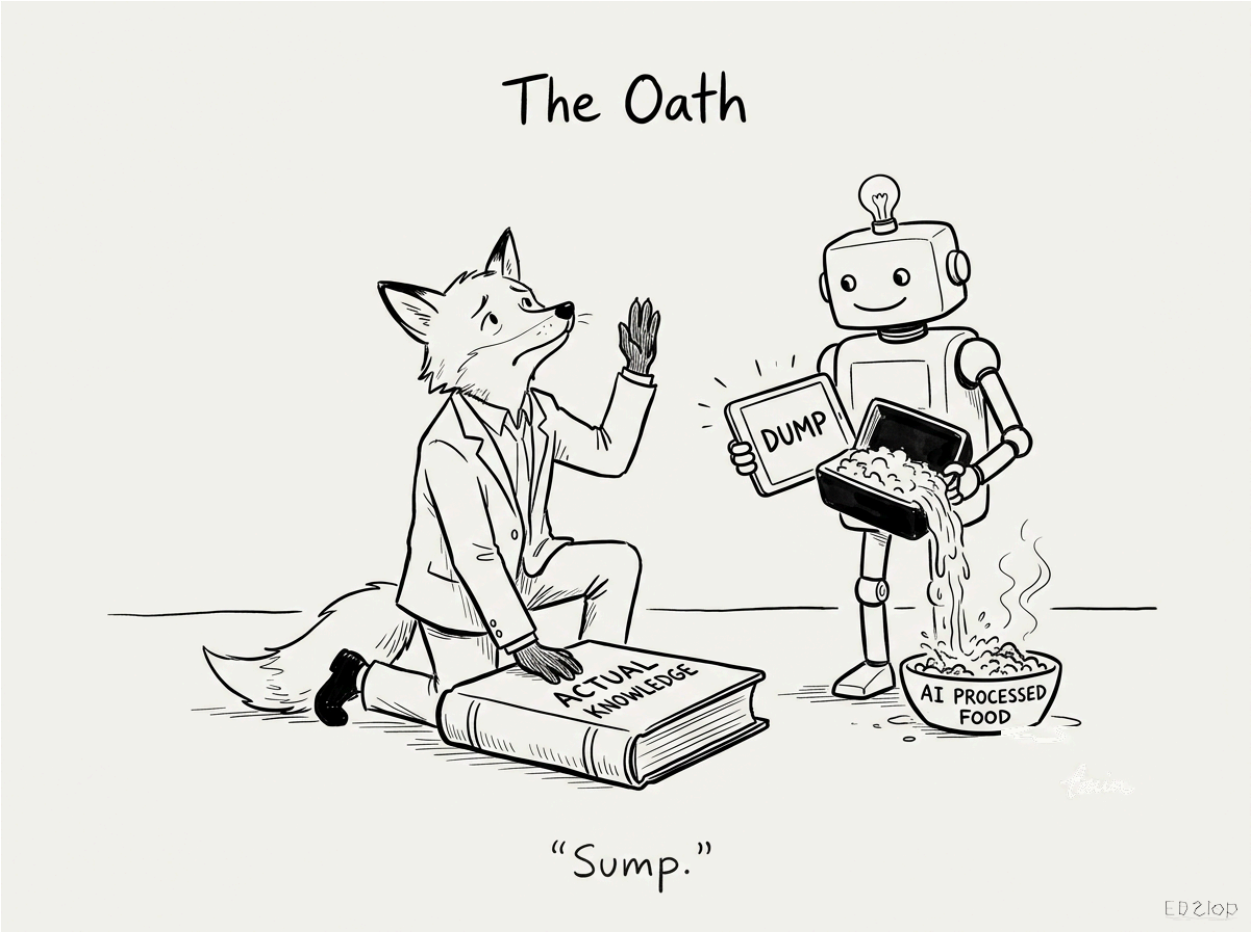
AI = Hyperfast Car - lights, signs, rails, laws, then the belt

Highway lights era

In the 1940s-60s, automobiles gained mass external safety: lights, signs, rails, laws. Those did not retire the need for devices the driver lives with every trip - seatbelts, later airbags. Ralph Nader's Unsafe at Any Speed (1965) forced the industry to treat crash safety as part of the car, not optional chrome.

We are still, with AI, in the highway-lights era. Company AI safety, vendor filters, and public rules are the lights. They do not close the session for you. SELFBELTING is the work-day version of Nader's fight: if the machine is fast, the human habit has to be as serious as buckling up before you merge.

A September 2026 paper by Solé and colleagues - Large-Language Models as a Cognitive Virus (arXiv:2609.03344) - describes chatbot use spreading through a population the way a workplace habit spreads. Easy to pick up. Harder to put down if everyone around you always asks the model first. Their charts are a warning sketch, not an IQ score. Keep a way back. Check a source yourself. Write a note by hand. Take a break.

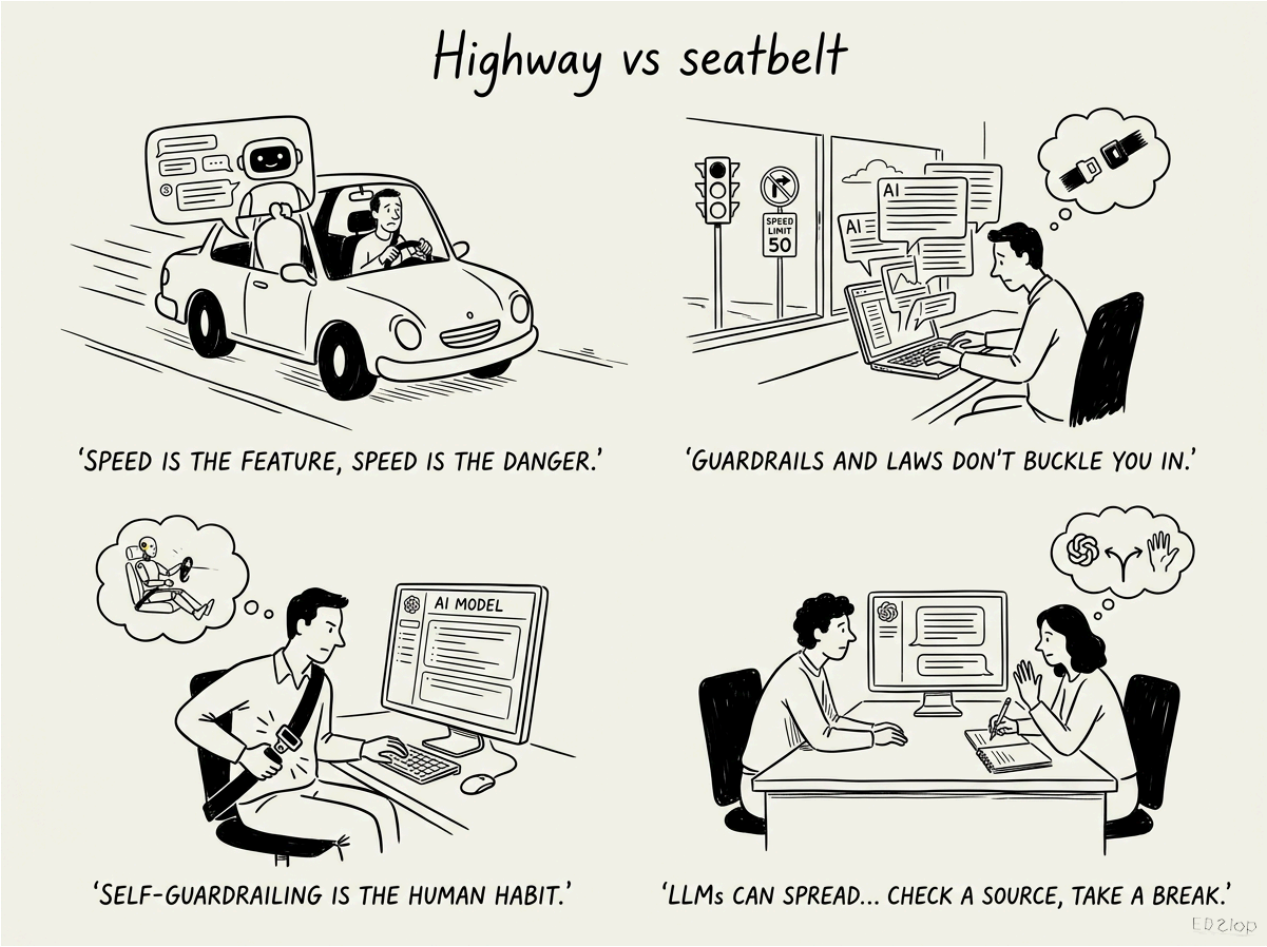


The Oath

The oath

I will not confuse feeling smarter after a chatbot dump with actually being smarter. AI output is useful processed food - not a full meal. I will work in 25-minute blocks, and I will not sit past 45 minutes without standing up and writing the point in my own words. I will pick a specialist tool (Agent specialization) instead of one “do everything” bot. When I close the window I can still say how and why, not only who / what / when.

This is the It’s Up To You rule. A firm can post AI policies. Only you stop the three-hour rabbit hole. Same lesson as late-1990s / 2000s CGI desks (including Pixar and Sony Imageworks): long hours plus a mouse gave many animators wrist injuries. The studio could post a memo; the wrist still belonged to the artist. With AI the strain is attention and memory, not only tendons.

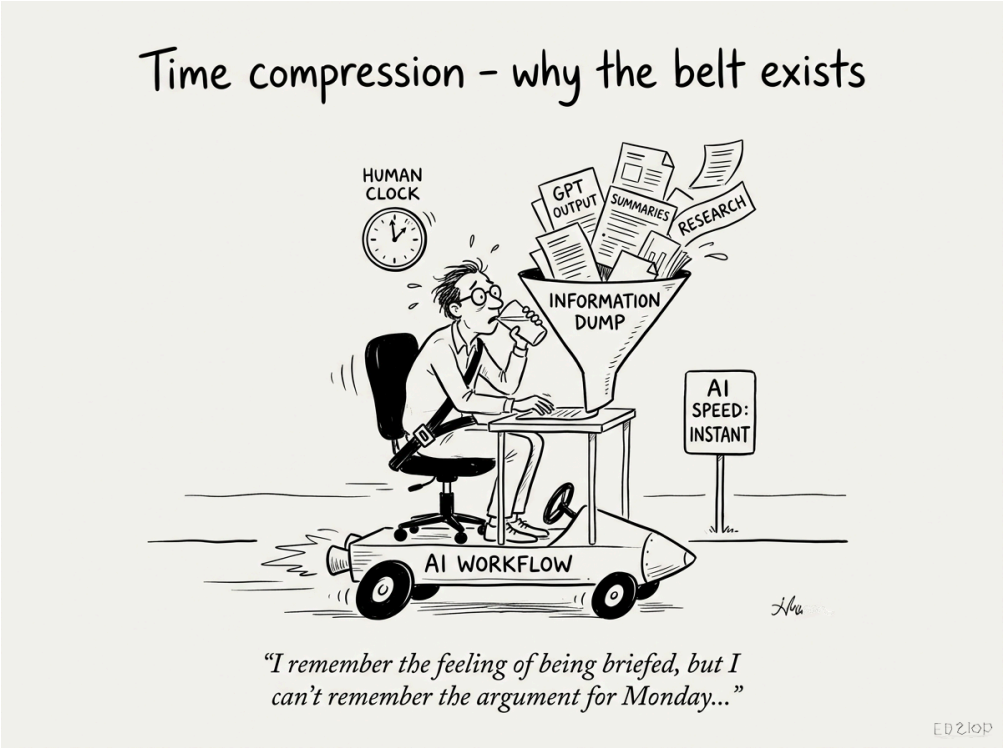


Highway vs seatbelt

Highway vs seatbelt

External safety is the road: lights, signs, rails, laws. Personal safety is the belt you live with every trip. Company policies and vendor filters can light the highway. They still do not sit in your chair, buckle you in, or close the laptop.

That is the split this page is named for. The history and the Solé paper sit in Highway lights era above. Here the habit is simple: treat the sitting like a merge. Destination first. Belt on. Then drive.



Time compression

Time compression - why the belt exists

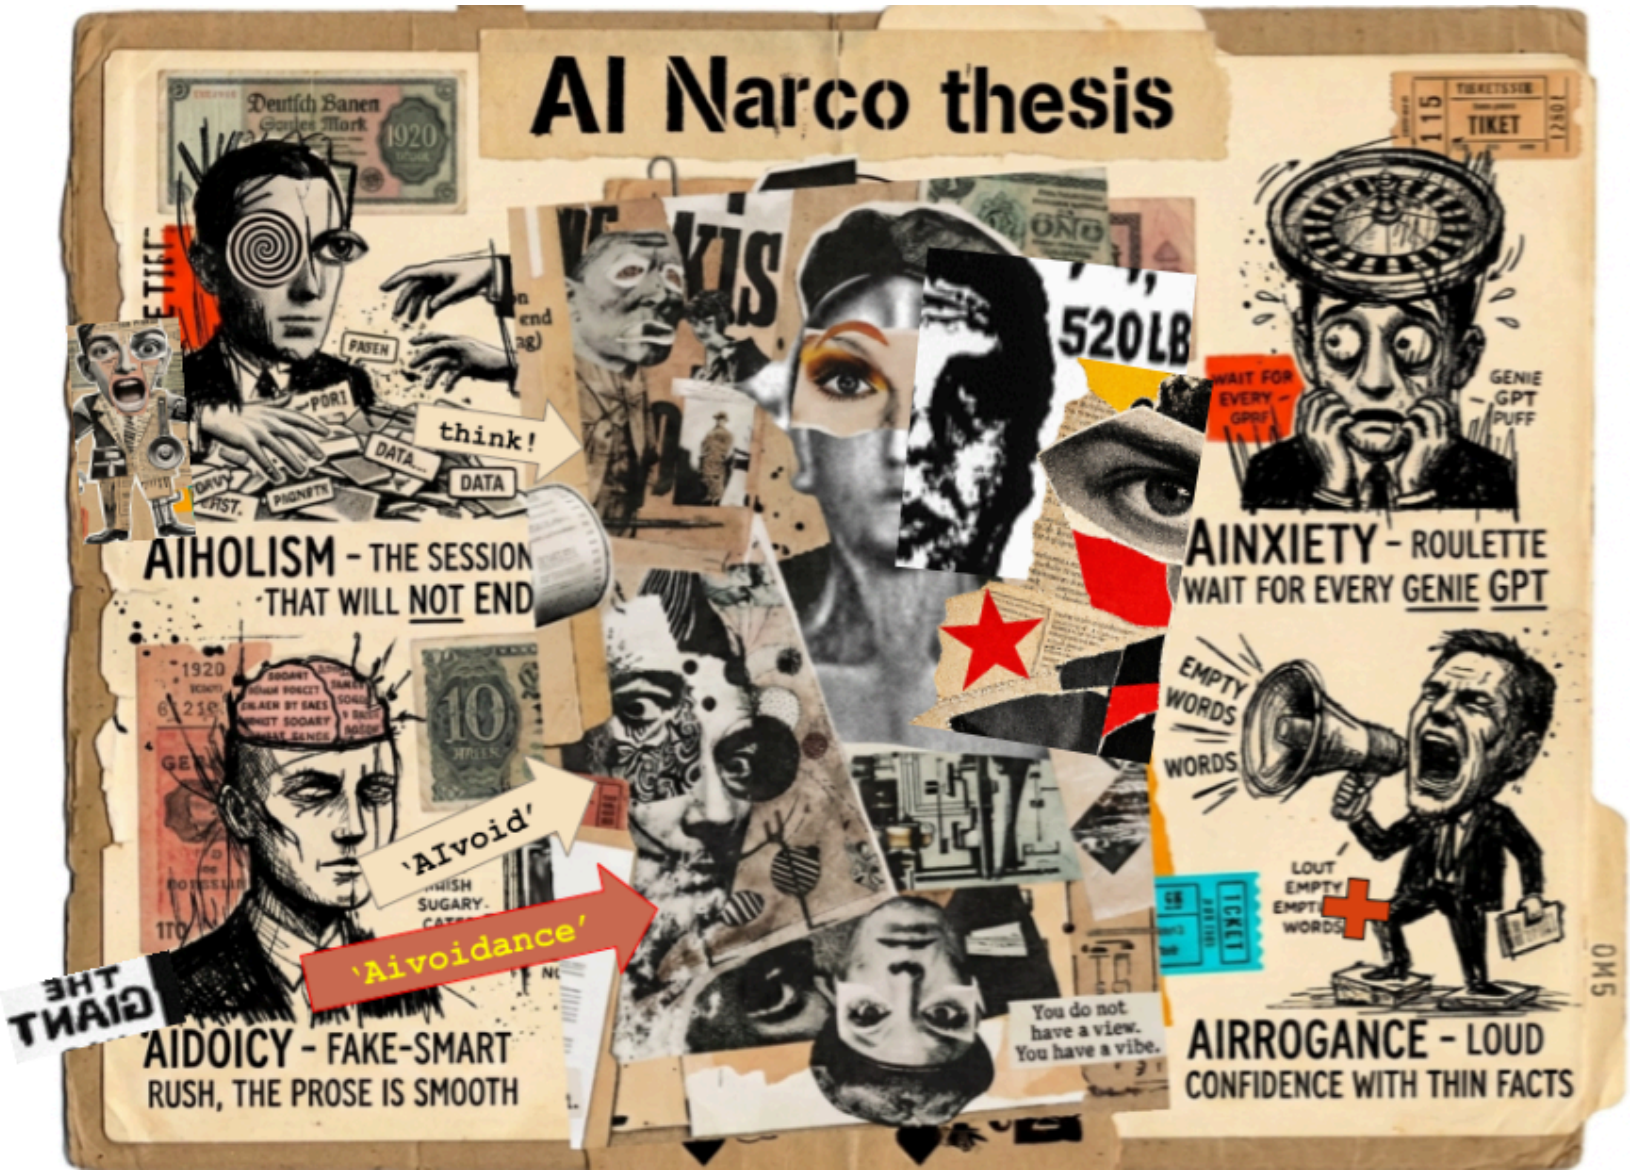
Before chatbots, a stack of filings, maps, and news took an afternoon. Now a model can pour a similar-looking pile onto your screen in one sitting. That is time compression: more information, less time to chew it.

Your brain still has a human clock. Digestion of a deal does not speed up just because the printer got faster. If you swallow the dump at highway speed, you remember the feeling of being briefed - not the argument you can defend on Monday.

That is why SELFBELTING uses short sittings. The vehicle is fast. You are not required to match its speed with your body.

There is a public Einstein story that is not General Relativity (GTR - gravity bending spacetime). A March 1929 New York Times anecdote had him tell a secretary: sit with a nice girl for two hours and it feels like a minute; sit on a hot stove for a minute and it feels like two hours. That is how duration feels under different stimuli, not a law of falling clocks. High-velocity AI hits that same inner clock. A job that used to mean an afternoon of walking, looking up, and writing now lands in seconds. Calendar time shrinks. The nervous system still spent something closer to the old afternoon. That mismatch is compressed labour, and it is why a short sitting can leave you wrung out.

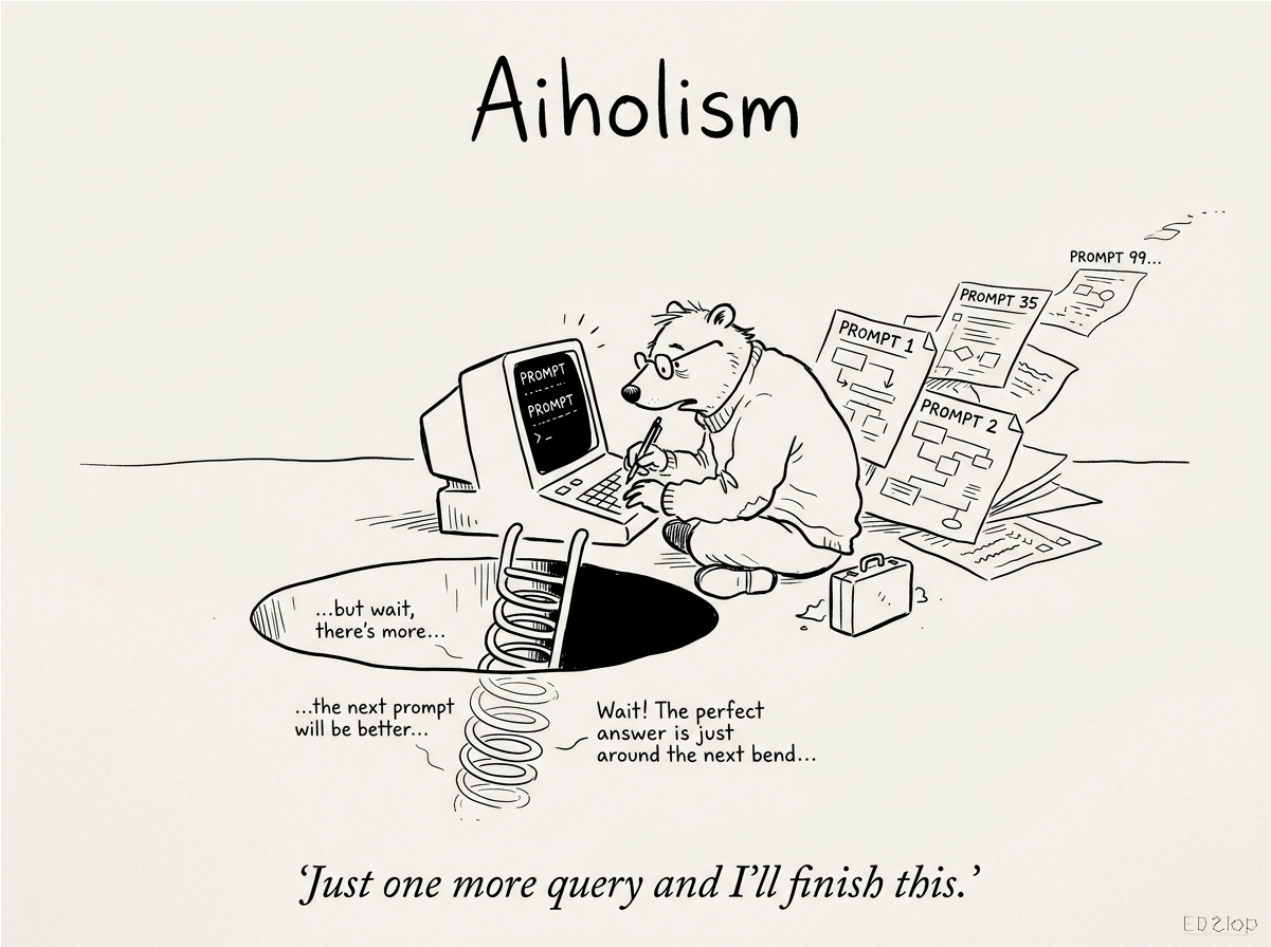
Same family as two other well-known warps, both psychology, not spacetime math. As years add up, a year is a smaller slice of the life already lived, and a routine year stores fewer new landmarks, so later years can feel faster. Places last seen as a child often look smaller on return: a smaller body was the measuring stick, and memory can store the room larger than the bricks. Do not let the model's seconds become your only ruler.



AI Narco thesis

Four named hazards

AI Narco thesis - four warning labels for AI-at-work. They are not hospital diagnoses. Each one is a different way the high-speed vehicle can get away from you: *Aiholism, Ainxiety, Aidiocy, Airrogance.*



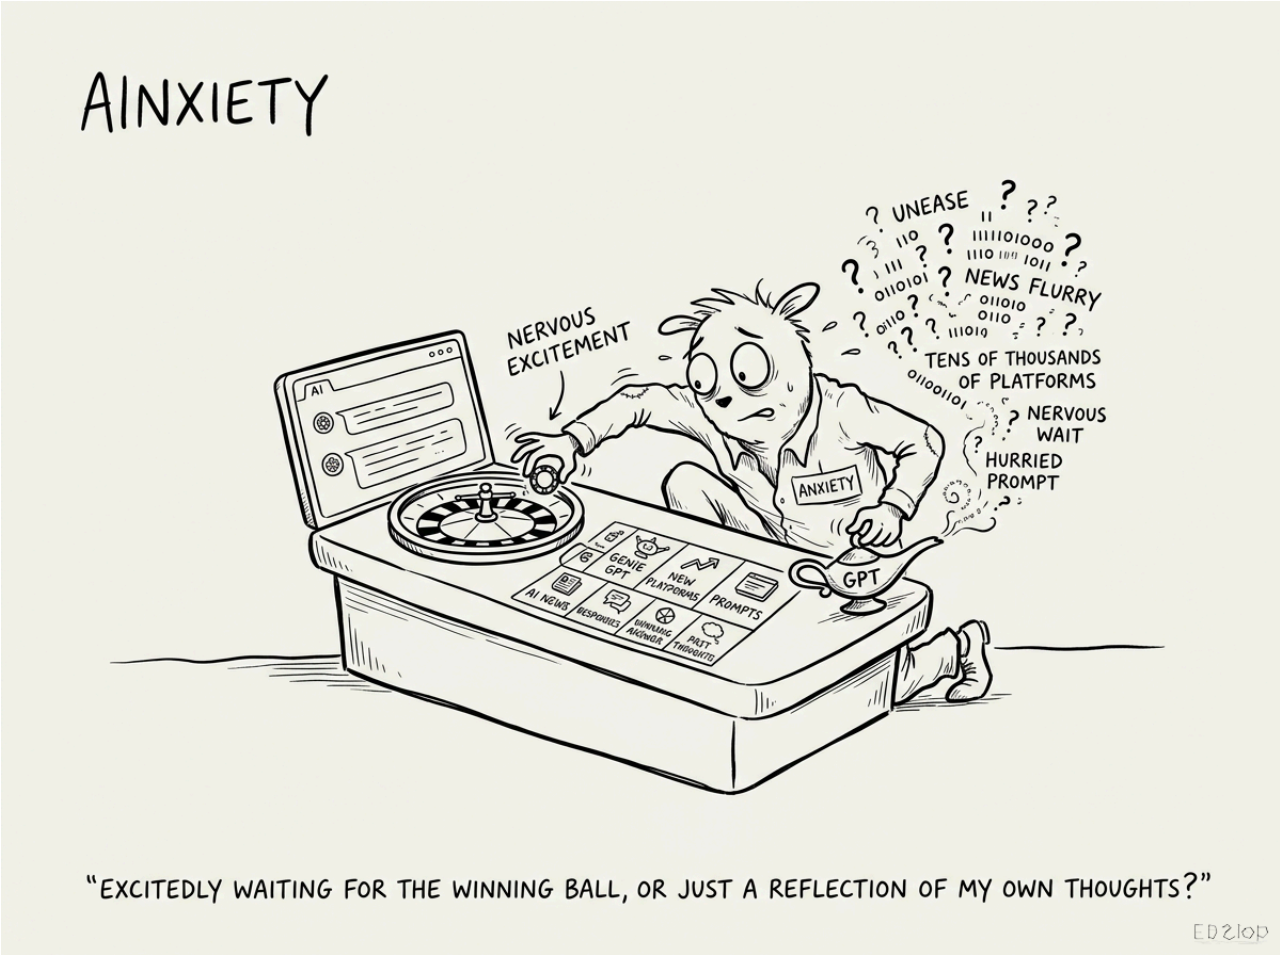
Aiholism

Aiholism

This is the session that will not end (also rabbitholing). You meant to check one fact. Two hours later you are still prompting because the next answer might be the one that finishes it.

It is the same hook as “one more exit” on a night drive, or one more ranked match after you already said you were done. The road is still there. Your judgment about stopping is what slipped.

The *tell* is not curiosity. The tell is that you cannot name the destination anymore - only the next prompt.



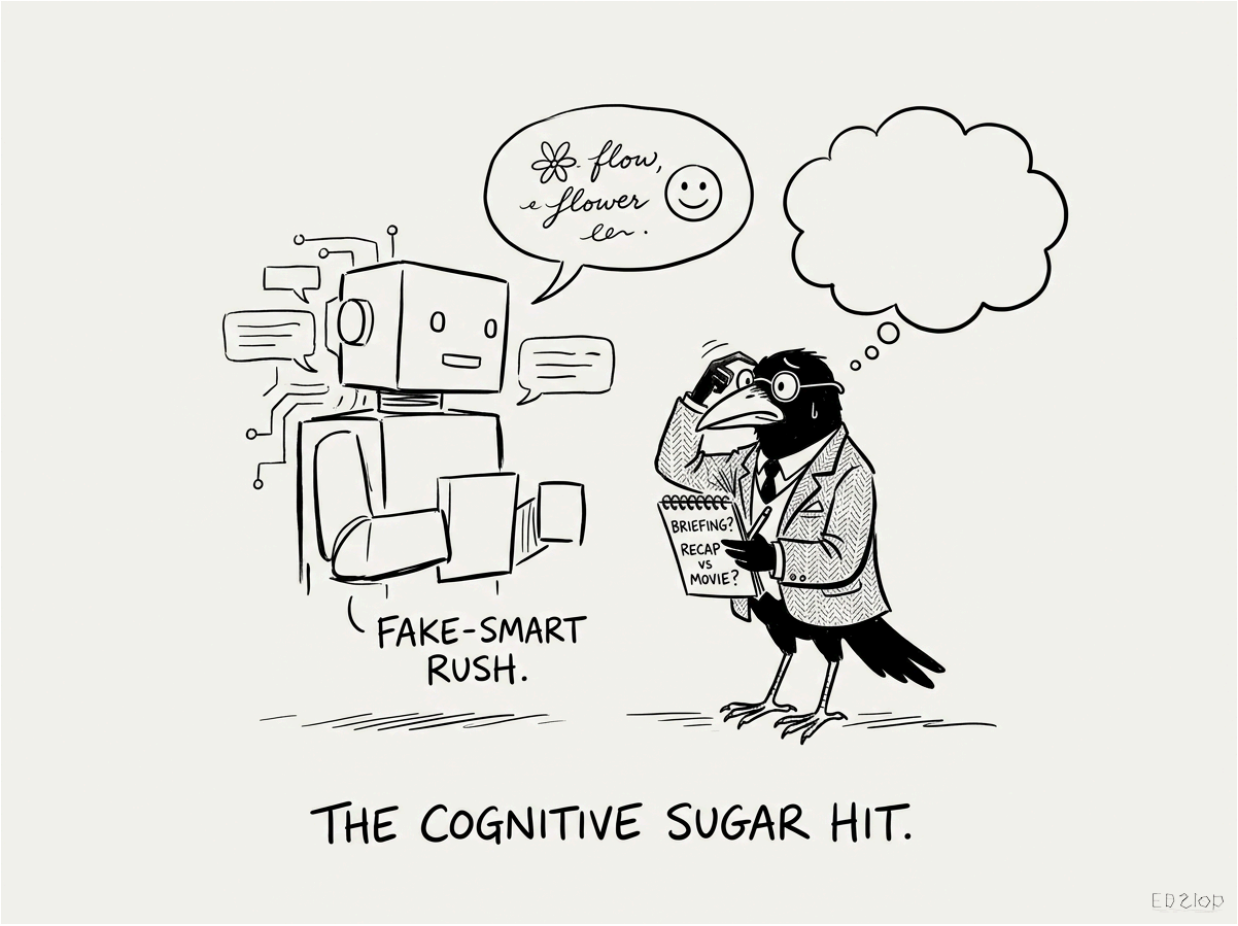
Ainxiety

Ainxiety

This is the unease when you are bombarded with anxiety-inducing NEWS on AI, in tandem with tens of thousands of sprouting AI platforms; then, once you have geared into a platform, you nervously wait for every new answer that this genie GPT lamp will puff out each time you rub it with an excited or hurried prompt.

It is like sitting at a roulette table waiting for a winning ball that is mostly a reflection of yours and others' past thoughts and beliefs. It is also closer to a driver who has used turn-by-turn GPS for every trip, then panics when the phone dies - not because they cannot drive, but because they stopped practicing the map in their own memory.

A short stretch of discomfort after you close the window is normal. If you cannot start the work at all without the bot, the belt was never on.



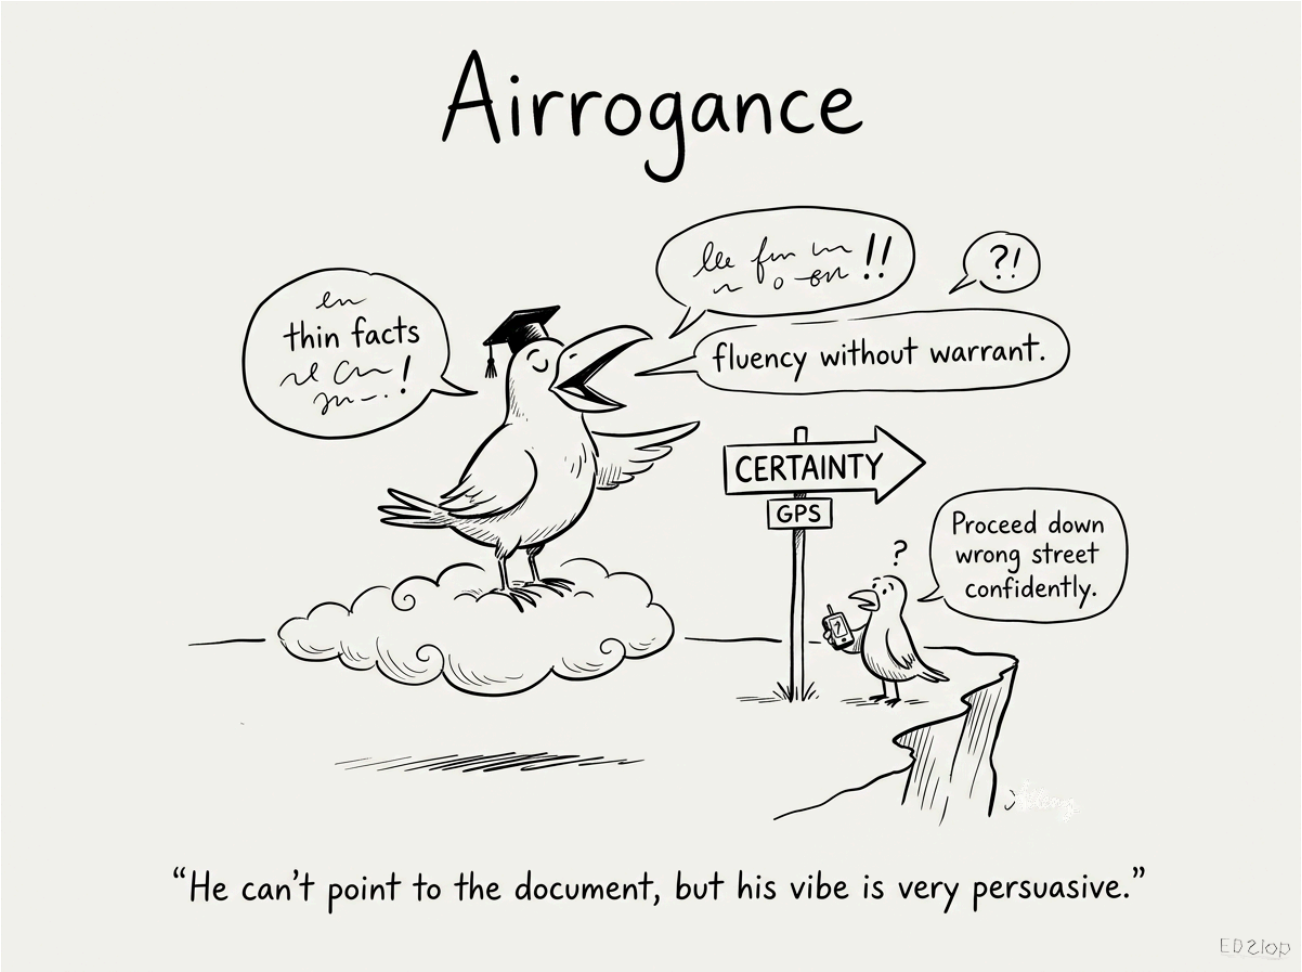
Aidiocy

Aidiocy

This is the fake-smart rush. The prose is smooth. You feel briefed. Next week you cannot explain the why without opening the chat again.

It is like reading a movie recap and believing you watched the film, or like a sugar hit that feels like a meal. Nootropic originally meant a substance meant to help the mind learn. Here the rush is the opposite: you feel sharper while the learning did not stick. See Extra-Nootropic / Dys-Nootropic.

If next week you need the chat open to retell the deal, the sitting was a briefing you did not keep.



Airrogance

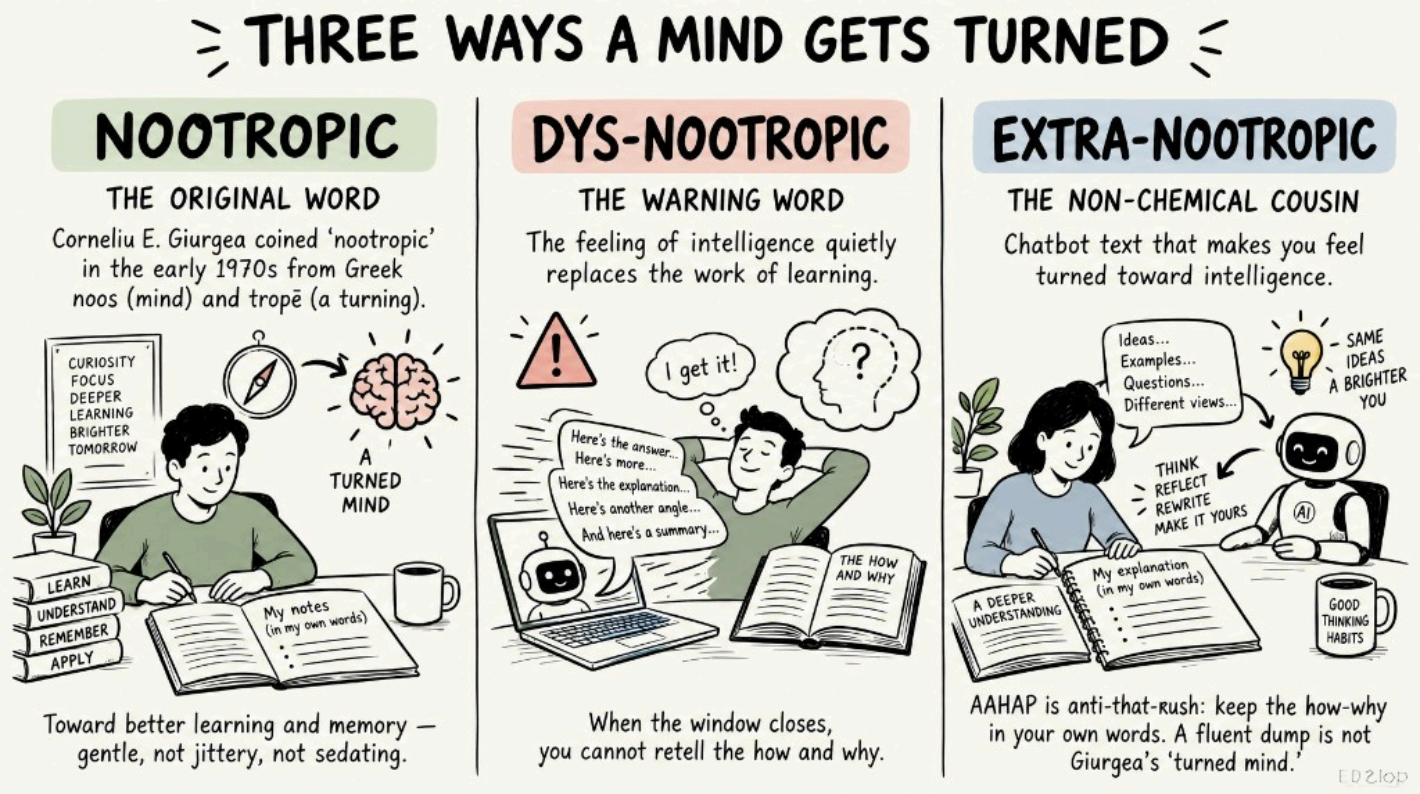
Airrogance

This is loud confidence with thin facts. The sentences sound board-ready. The sources are thin, circular, or missing - and you still walk into the room sure.

It is a GPS that speaks in a calm voice while sending you down the wrong street. Fluency is not the same as a warrant. The public line is AI that makes people stupid-confident (LinkedIn post).

The belt here is simple: if you cannot point to the filing, the map, or the call note, you do not have a view. You have a vibe.

An MIT Media Lab study (Kosmyna and colleagues, Your Brain on ChatGPT - arXiv:2506.08872; TIME summary) asked 54 adults, ages 18-39, to write short SAT-style essays. One group used ChatGPT, one used Google, one used only their own heads. Brain sensors showed the ChatGPT group was the least engaged. Over sessions they copied more and later could barely quote their own essay. The unaided group stayed sharpest. Google sat in the middle. Small study, not final science.



Three ways a mind gets turned - Nootropic, Dys-Nootropic, Extra-Nootropic

Nootropic - the original word, then our warning words

Corneliu E. Giurgea coined Nootropic in the early 1970s from Greek noos (mind) and tropē (a turning). He meant a substance that would turn the mind toward better learning and memory, while staying gentle - not a jumpy stimulant, not a knockout sedative. That is the frame.

A real nootropic, in his sense, was supposed to leave you more able when the pill was gone. *Extranootropic* is our name for the non-chemical cousin: chatbot text that makes you feel turned toward intelligence. *Dysnootropic* is when that feeling quietly replaces the work of learning: you cannot retell the how and why once the window is closed.

Rub the genie lamp

Rub the Genie Lamp - *the wish addict*

A prompt is a rub on the lamp. You ask. Something large comes back - a memo, a list, a picture, a clip - faster than any intern could fetch it.

Fairy tales already knew the catch. The genie is fast. The genie does not owe you the wish you meant. If you keep rubbing instead of deciding, you are not using a tool. You are waiting on a spirit.

SELFBELTING's rule: one clear wish (the destination sentence), then you inspect what came out. You do not keep rubbing because the next wish might be prettier.

Creative roulette

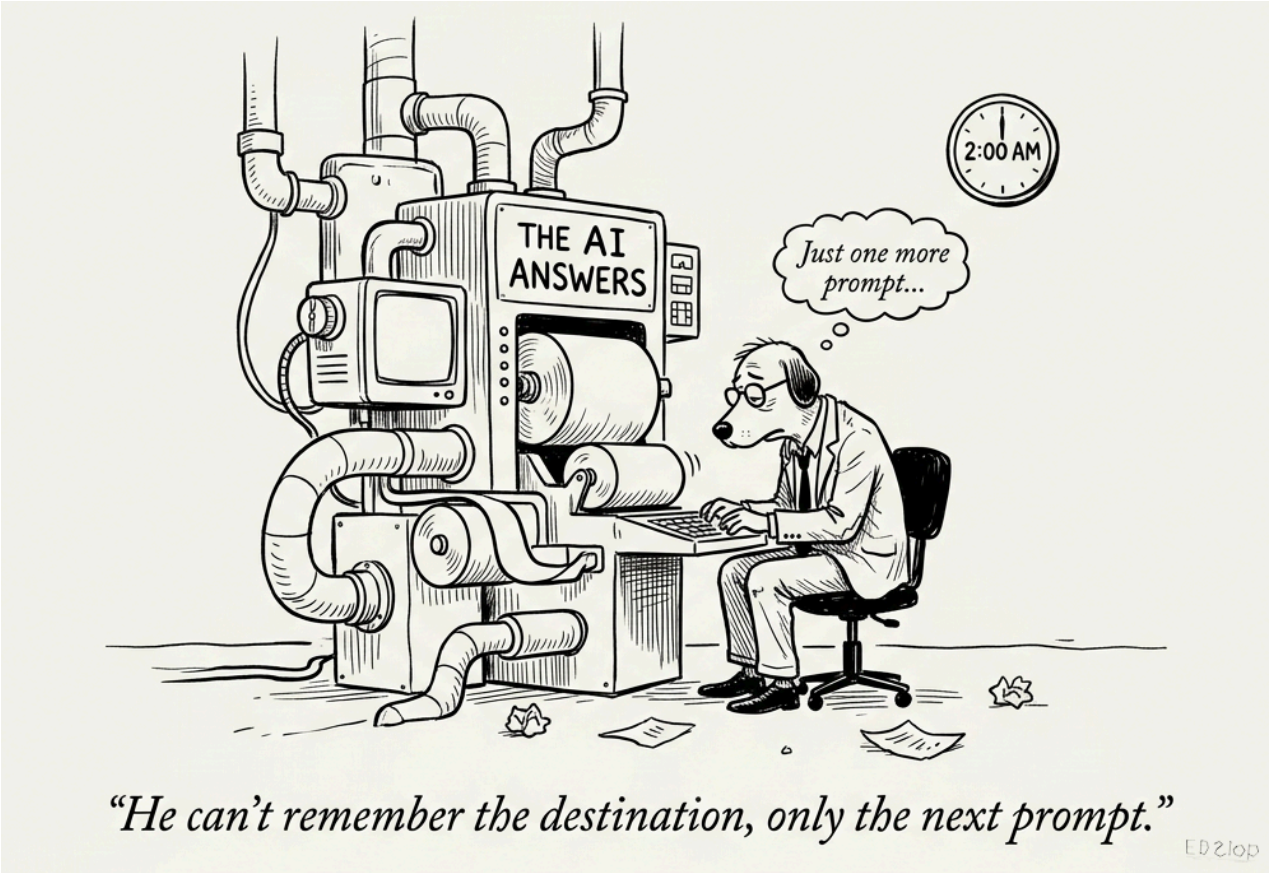
Creative Roulette - *the hopeful wait*

Text chat is fast. Image, video, and music models add a second hook: you wait while the machine rolls. That wait is not a loading bar in the ordinary software sense. You are hoping this spin is the good one.

Generative models are stochastic at the core - they sample, they do not photocopy a single true picture. That is why the same prompt can yield three different stills. It is also why the wait feels like a dice roll, a roulette wheel, or the pause before a lottery scratch: maybe this ticket is the art.

That hopeful wait is easy to chain. One more IMGN still. One more 360fy pass. One more “make it cinematic.” You are not lazy. You are in a reward loop that pays off on an unpredictable schedule - the same family of hook as a scratch ticket, not a proof you have a gambling disorder.

Belt for Georgia and any art model: set the destination (what the picture is for), cap the spins, and walk away with a chosen frame. Do not let the wheel keep you in the chair past the session clock.



He cannot remember the destination, only the next prompt

Session Clock - *how long to stay in the tool*

There is no magic lab number that says "always stop at minute 27." We picked three easy numbers you can remember. An MIT writing study used about 20 minutes per sitting. Many offices already use a 25-minute focus timer (Pomodoro). We add a 45-minute hard stop so your AI copilot or ChatGPT time does not eat half your afternoon. While you are in that sitting, rest your eyes every 20 minutes: look about 20 feet away for 20 seconds.

Who	Working block	Hard stop	After you stop
Under 18 / school	20-25 min	25 min	10+ min off the tool. Draft first, then ask AI.
18-25	25-35 min	35 min	8-10 min walk or handwritten recap.
Busy professional (default)	25 min	45 min	10 min off. Treat it like a drive: start, destination, stop.
55+	20-30 min	30 min	10 min off. Shorter is about fatigue, not a diagnosis.

Default for everyone: 25 minutes on, then a real break. If the hunt is hot, you may stretch toward 45 minutes once - then you stand up. After the break you should be able to retell the logic in your own words. If you cannot, the model did the thinking and you only watched.

AERL - Analogical Experiential Relational Learning

AERL - learn with stories, sketches, and bodystorming

Do not learn by swallowing research papers.AERL (formerly ARL) means Analogical Experiential Relational Learning: we explain hard ideas with pictures and everyday stories (highway, seatbelt, soup can, processed food). Then you bodystorm: write or sketch what you just learned so it is yours. Same idea as explaining “search vs chatbot” with a librarian vs a lawyer - not a page of equations. If this habit cannot be told to a busy professional in ordinary sentences, it is not ready.

What was checked (and what was not)

1. Read: arXiv:2609.03344 - Solé and colleagues, Large-Language Models as a Cognitive Virus (how chatbot habits can spread on a team).
2. Read: arXiv:2506.08872 - Kosmyna / MIT, Your Brain on ChatGPT, plus the TIME write-up and the MIT Media Lab page.
3. Background word: Nootropic - Giurgea, early 1970s: a substance meant to turn the mind toward learning and memory without acting like a stimulant or sedative. Frame for extra- / dys-nootropic on this page.
4. Operator notebooks, 7-9 Mar 2026: AAHAP, AAMGAP, AERL, seatbelt habit, fake-smart rush, genie-lamp / generative wait. Those pages are not online.
5. Opened by link, full post not fully loaded here: LinkedIn - “AI stupid confident”.
6. Facebook share - we could not read the body from here. Treat as unverified until you open it yourself.
7. Felt-time check (Time compression addendum): Quote Investigator - hot stove / nice girl (NYT March 1929 anecdote; similar line in Ray Cummings fiction, 1921-22). Not a derivation of General Relativity. Aging “years feel faster”: Wittmann; Friedman and Janssen 2010 (effect is real for long spans, modest). Childhood places looking smaller: own-body-size / Poincaré measuring-stick (van der Hoort, Ehrsson). Named management concept: AI-induced temporal compression (Academy of Management 2025). No claim that 7.5 hours of AI work equals a fixed 15-18 hours.
8. This is not a clinic, and it is not a claim that a 45-minute AI session/sitting causes proven brain damage. The honest work risk is: you forget what you “wrote,” you cannot explain the why, and the habit of always asking the bot first gets sticky.

Practice - five moves

Practice - five moves when you sit down with AI

Use this like a pre-flight list. Same moves whether you are in ChatGPT, or another AI copilot.

Write the destination first

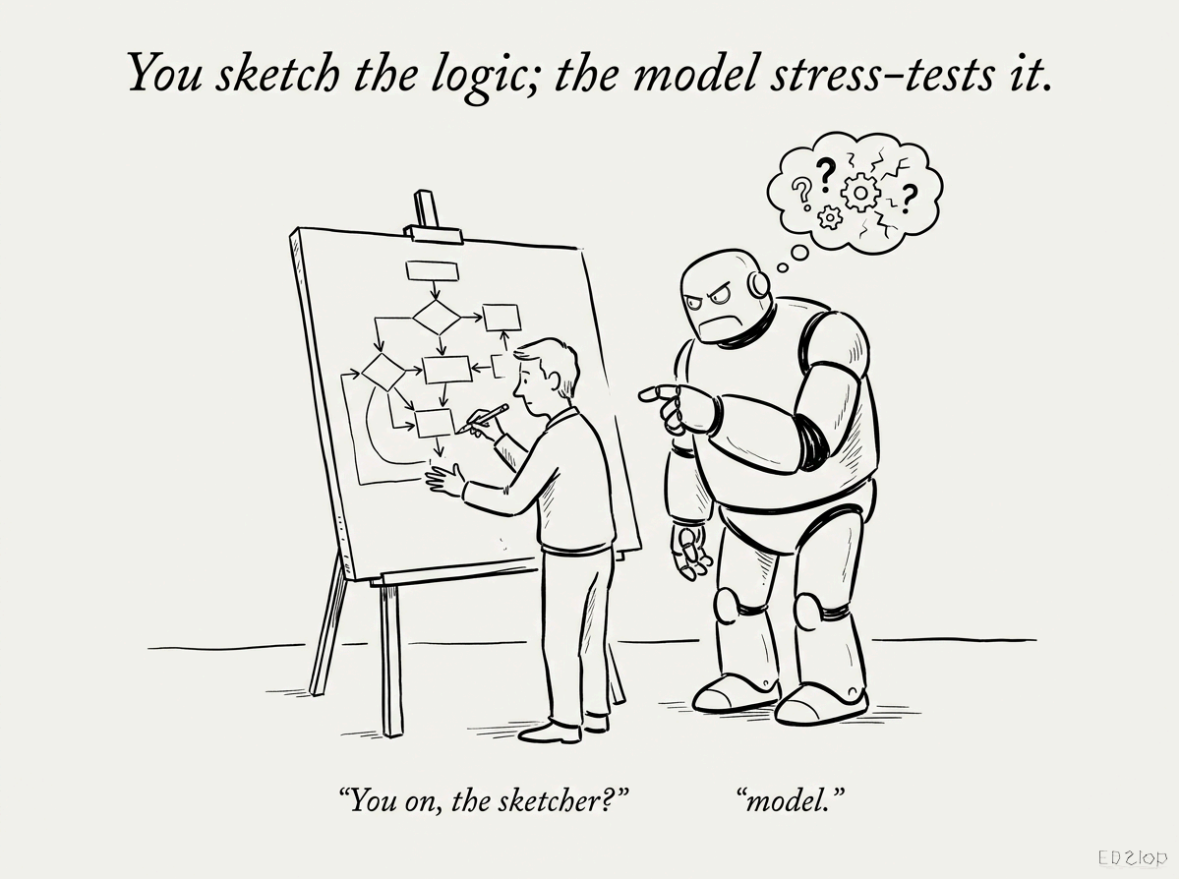
1. Write the destination first. Before you type the first prompt, write one ordinary sentence: what decision or deliverable you need when you stand up , "I need a clean why-this-asset-now for the Monday IC pack"). If you cannot say that in one sentence, you are not ready to open the tool.

Think of yourself as a movie director, and AI as your actor: ready for well-thought-out, stepwise instruction(s).

Set a 25-minute timer

2. Set a 25-minute timer, then protect your eyes. Start the clock before the first paste. You are allowed to work, not to drift. Every 20 minutes, look about 20 feet away for 20 seconds so the screen does not glue you in.

When the 25 minutes end, you stop the sitting (director/actor session) even if the chat is still interesting.



You sketch the logic; the model stress-tests it

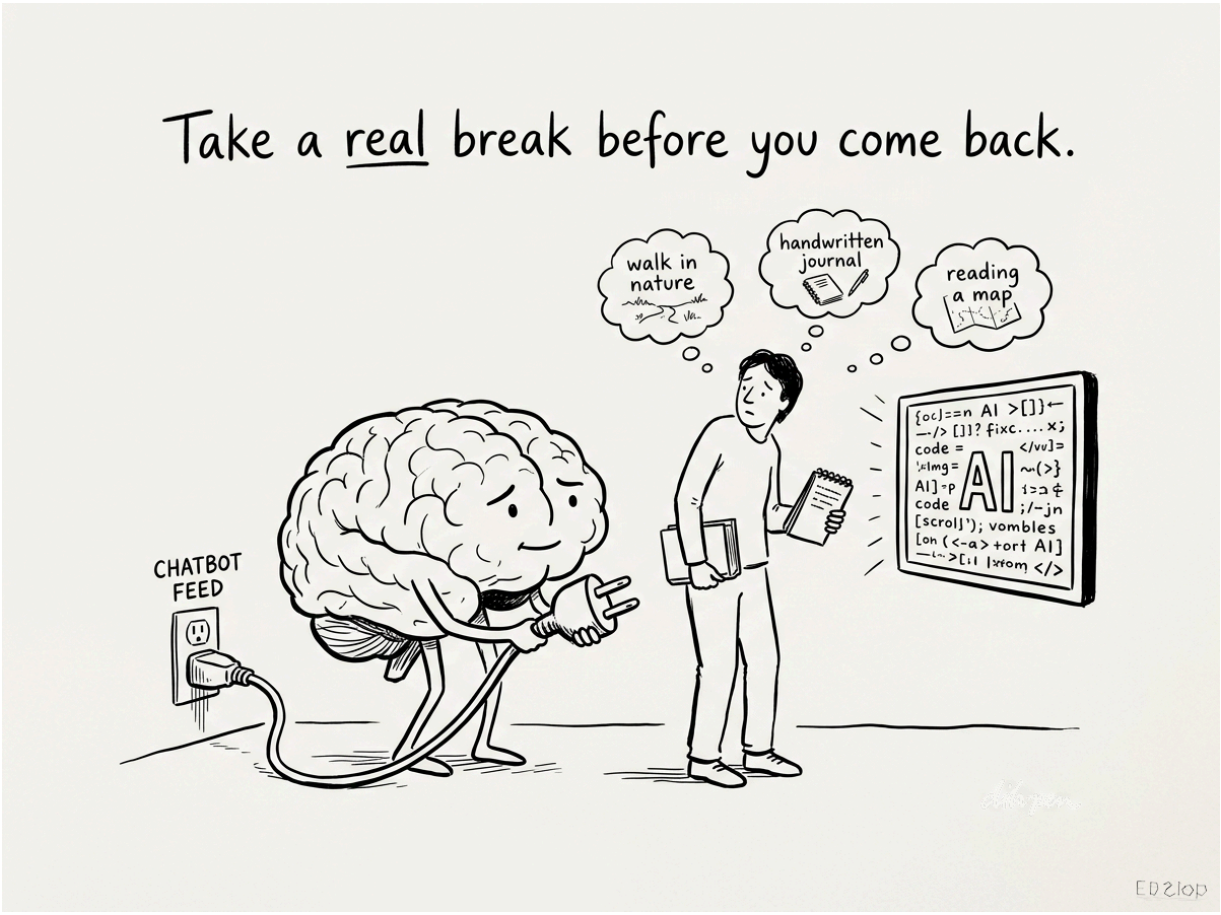
3. You sketch the logic; the model stress-tests it. Draft the how and why yourself (bullets are enough). Then ask the model to poke holes, find missing sources, or tighten wording. Do not dump the whole job into the box and wait for a finished memo.

If the model writes the argument, you will not own it in the room.

Close the tool and retell it cold

4. Close the tool and retell it cold. When the timer stops, look away from the screen and say (or jot) the point in your own words: what you decided and why. If your mind is blank, you did not do the work - you borrowed the model's fluency.

- *That is the cue to shorten the next sitting, not to prompt again immediately.*



Take a real break before you come back

5. Take a real break before you come back. Walk, write by hand, or read a human source (filing, map, call notes) that is not another chatbot. Only then start a new 25-minute sitting. A “quick follow-up prompt” with no break is how a 25-minute block becomes two hours.

You are still the person on the deal. SELFBELTING is the timer, the break, and the refusal to confuse fluent text with a decision you can defend.

The collection of collages which have been included in this SELFBELING guide are a new lineage of Dada and Dadaism art movement, called Dys-dada. Here their lineage and purpose are defined and explained in simplespeak as well as techspeak.

Simplespeak Definitions

Dada & Dadaism (Est. 1916)

Dada art movement started in 1916 at a noisy Zurich club called Cabaret Voltaire, while a world war was on. Artists cut paper, shouted nonsense, and made ugly jokes so official "good taste" could not hide the slaughter. The name Dada itself was meant to sound like baby talk, not like a school with a syllabus. Hugo Ball and Tristan Tzara wrote manifesto-shouts; the point was refusal, not a five-year plan. Collage, noise, and nonsense were the tools. Then Dada spread, fought itself, and mostly ended or became something else.

Neo-Dada (Est. 1950s)

Neo-Dada is what critics later called some 1950s-60s artists who picked the collage joke back in peacetime America. Robert Rauschenberg glued real beds and tires into paintings. Jasper Johns painted flags and targets everyone already knew. Marcel Duchamp's "this can be art" objects were still in the room. Happenings let the crowd be part of the piece.

Dys-Dada (Est. 2026)

Dys-Dada is the 2026 version of the original Dadaist rebellion, aimed at AI slop and slogan-smooth generation. The dys- means the culture is turned the wrong way: too much frictionless picture, too little hand. It is counterpropaganda propaganda - *depropaganda* - a poster that talks back to posters, including the ones a model can spit out all night. If the style becomes another fluent brand, it has already lost.

Techspeak Definitions

Dada, Neo-Dada & Dys-Dada

Dys-Dada (also written Dys-dada or DYSDADA) sits after two older collage rebellions.

The Dada Rebellion: The Dada art movement began in 1916 at Cabaret Voltaire in Zurich, opened by Hugo Ball and Emmy Hennings while World War I burned around a neutral street. Tristan Tzara, Richard Huelsenbeck, Marcel Janco, Sophie Taeuber-Arp, and Jean Arp used collage, noise, and nonsense against the culture that had marched into the war.

The word Dada was a nonsense brand - a child's hobbyhorse in French, a yes-yes in Romanian - so it would not sound like a tidy academy. Ball read a manifesto in July 1916; Tzara's

better-known Dada Manifesto was printed in 1918. Dada said no to official taste, patriotic slogans, and the idea that art must be beautiful or useful. It spread to Berlin, Paris, New York, and Cologne, then burned out or turned into other movements, including Surrealism.

The Neo-Dada Rebellion: Neo-Dada is the 1950s-60s revival, mostly in the United States, named later by critics such as Barbara Rose. Robert Rauschenberg and Jasper Johns put flags, beds, tires, and newsprint into the picture so art and daily life were no longer two rooms. Marcel Duchamp was still in New York; his readymades were the grandfather in the apartment. Allan Kaprow's Happenings and John Cage's chance pieces made the audience part of the work.

That mix helped open Pop Art, Fluxus, and later performance - still collage, still joke, now in a consumer-image world rather than a world-war cabaret.

The third rebellion (soft rebellion for now) is Dys-Dada.

Dys-Dada is the post-4IR age cut of that *reactivist* lineage (*Reactivists* don't start off as activists, per say; they situationally and often subconsciously turn reactive when faced with mass forms of cultured idiocy, self-deprecating complacency, or overconformity). The Dys-Dadaist job is counterpropaganda propaganda - *depropaganda*: use the poster's shout against the poster's lie, including the lie that more generation is always more culture.

Uncle Sam, tickets, banknotes, and circuit boards share one folder so the machine's junk and the human hand sit at one table. Copyright 2026 on the plates is the analog claim: a person cut this. Wear it as a seatbelt mark, not as a new church: if the collage starts selling the same fluency it mocks, it has failed.
